CS 200 Lab 07b: Inheritance

Topics

- Classes
- Inheritance

Starting out

Make sure to download the following code files:

- main.cpp
- Question.hpp
- Question.cpp
- Quizzer.hpp
- Quizzer.cpp

Starting off, we won't use all the files at first.

Create a new project, and only import **Question.hpp** and **Question.cpp**, and create **main.cpp** with just the standard program starting point.

Start off with the code on the next page.

Question.hpp

```
1 #ifndef _QUESTION_HPP
   #define QUESTION_HPP
4 #include <string>
5 #include <iostream>
   using namespace std;
   class Question
8
9
   };
10
11
   class TrueFalseQuestion: public Question
12
13
14
   };
15
   {\bf class} \ \ {\bf Multiple Choice Question} \ : \ {\bf public} \ \ {\bf Question}
16
17
   };
18
19
20 #endif
```

Question.cpp

```
#include "Question.hpp"
```

main.cpp

```
#include <iostream>
#include <string>
using namespace std;

#include "Question.hpp"

int main()
{
    return 0;
}
```

By Rachel Morris 2 of 17

The Question family

First, we will build out the **Question** base class.

We aren't going to create any Question objects, but it is the starting point for all other questions - this class will contain that which is in common to all other Questions.

Question class

Member variables

Accessibility	Data Type	Variable Name
protected	string	$m_{question}$ Text

Member functions

Accessibility	Return Type	Function Name	Parameters
public	void	Display	-
public	void	SetQuestionText	string text

void Display()

Use a \mbox{cout} statement to display the value of $\mbox{m_questionText}$.

```
Display the value of the variable...

cout << VARIABLE << endl;

The variable is m_questionText
```

By Rachel Morris 3 of 17

void SetQuestionText(string text)

This function will be reused by the child classes. Write an assignment statement that will set the member variable, $m_questionText$, to the value of the parameter passed in.

Assignment statement

VARIABLE = VALUE;

The parameter is string text

The variable is m_questionText

Common mistake

Make sure that you're not *redeclaring* the variable m_questionText – You shouldn't be using its data type here.

 $m_questionText$ is already a **member** of the Question class. Just use it by name.

Testing

Before continuing, test your Question class!

Within main(), do the following:

- 1. Declare a variable whose data-type is **Question**.
- 2. From this variable, call the SetQuestionText function and pass in a value.
- 3. Call the variable's Display function.

When you run the program, your question text should be displayed to the screen.

TrueFalseQuestion class

This question type will display the question, then ask the user to enter true or false, and then figure out if they answered correctly.

This means that we need functions to set whether *true* or *false* is the correct answer, as well as to check the user's response.

Member variables

Accessibility	Data Type	Variable Name
private	string	m_correctAnswer

Member functions

Accessibility	Return Type	Function Name	Parameters
public	void	Display	-
public	void	SetCorrectAnswer	string correctAnswer
public	bool	CheckAnswer	string userAnswer

void Display()

This function should call the parents' version of the Display function first, then add its own unique code in.

```
void TrueFalseQuestion::Display()
{
Question::Display();
}
```

Afterward, display another message, asking, "True or false?"

By Rachel Morris 5 of 17

void SetCorrectAnswer(string correctAnswer)

This function is responsible for assigning the *value* of the parameter correctAnswer to the member variable m_correctAnswer.

bool CheckAnswer(string userAnswer)

This function receives the answer that the user gave, as the parameter ${\tt userAnswer}$.

This function should compare userAnswer to the member variable m_correctAnswer in order to decide if the user was correct or not.

- If userAnswer and m_correctAnswer match, then return true.
- Otherwise, return false .

Testing

Before continuing, test your TrueFalseQuestion class!

Within main(), declare a TrueFalseQuestion object. Use SetQuestionText to set its question and SetCorrectAnswer to set the correct answer, then use Display to view the question text, and CheckAnswer to see if it correctly detects right and wrong answers.

By Rachel Morris 6 of 17

```
1
  int main()
2
3
       TrueFalseQuestion tfQuestion;
4
       tfQuestion.SetQuestionText("Is Kansas a state?");
5
       tfQuestion.SetCorrectAnswer( "true" );
6
7
       tfQuestion.Display();
8
9
       string answer;
10
       cin >> answer;
11
12
       bool result = tfQuestion.CheckAnswer( answer );
13
       if ( result == true )
14
            cout << "Correct answer!" << endl;</pre>
15
16
       else
17
            cout << "Wrong answer!" << endl;</pre>
18
19
       return 0;
20
```

```
Is Kansas a state? (true/false): true 
Correct answer!
```

By Rachel Morris 7 of 17

MultipleChoiceQuestion class

This type of question will display four options for the user to choose from. The user will select 1, 2, 3, or 4, and only one answer will be right.

This means that we need functions to set the text for options 1, 2, 3, and 4, as well as store whether option 1, 2, 3, or 4 is the correct answer.

Member variables

Accessibility	Data Type	Variable Name
private	string array, size 4	m_answers
private	int	$m_{correct}Answer$

Member functions

Accessibility	Return Type	Function Name	Parameters
public	void	Display	-
public	void	SetAnswerChoices	string a, string b,
			string c, string d
public	void	SetCorrectAnswer	int correctAnswer

void SetAnswerChoices(string a, string b, string c, string d)

Set each of the elements of the array m_answers to one of the parameters.

```
Answer \#0 = a Answer \#1 = b
Answer \#2 = c Answer \#3 = d
```

void Display()

Once again, call the Question class' version of Display(), and then use a **for loop** to iterate over all 4 options in the member array, m_answers, displaying them to the screen.

void SetCorrectAnswer(int correct)

The parameter correct stores the *index* of the m_answers element that is storing the correct answer.

Store this value in the m_correctAnswer member variable.

bool CheckAnswer(int userAnswer)

This function receives the answer that the user gave, as the parameter userAnswer .

This function should compare userAnswer to the member variable m_correctAnswer in order to decide if the user was correct or not.

- If userAnswer and m_correctAnswer match, then return true.
- Otherwise, return false .

Testing

Write a test that creates a MultipleChoiceQuestion, sets the question with SetQuestionText , sets the answer choices with SetAnswerChoices , sets the correct answer with SetCorrectAnswer , displays the question with Display , and checks if the user's answer was right with CheckAnswer .

By Rachel Morris 9 of 17

```
1
   int main()
2
3
       MultipleChoiceQuestion mcQuestion;
4
       mcQuestion.SetQuestionText("What is the capital of
5
      Kansas?");
       mcQuestion.SetAnswerChoices("Topeka", "Wichita",
6
                                      "Kansas City", "Boise")
8
       mcQuestion.SetCorrectAnswer( 0 );
9
10
       mcQuestion.Display();
11
       int answer;
       cout << ">> ";
12
13
       cin >> answer;
14
15
       bool result = mcQuestion.CheckAnswer( answer );
16
       if ( result == true )
17
18
           cout << "Correct answer!" << endl;</pre>
19
       else
20
           cout << "Wrong answer!" << endl;</pre>
21
22
       return 0;
23
```

```
What is the capital of Kansas?

OPTIONS:

0. Topeka

1. Wichita

2. Kansas City

3. Boise

>> 2

Wrong answer!
```

CS 200 Summer 2017 Lab 07b

The full program

Now that your Question classes are working, import in the **Quizzer.hpp** and **Quizzer.cpp** files to your project, and overwrite **main.cpp** with the file provided.

Quizzer.hpp

```
#ifndef _QUIZZER_HPP
  #define _QUIZZER_HPP
  #include "Question.hpp"
4
5
6
   class Quizzer
7
8
   public:
9
       Quizzer();
10
       void AddTrueFalseQuestion( TrueFalseQuestion* q );
11
12
       void AddMultipleChoiceQuestion(
      MultipleChoiceQuestion* q );
13
14
       void Run();
15
16
   private:
17
       TrueFalseQuestion* m_tfQuestions[3];
18
       MultipleChoiceQuestion * m_mcQuestions [3];
19
20
       int m_count_tfQuestions;
21
       int m_count_mcQuestions;
22
   };
```

Quizzer.cpp

```
#include "Quizzer.hpp"

#include <iostream>
#include <string>
using namespace std;

Quizzer::Quizzer()

m_count_mcQuestions = 0;
m_count_tfQuestions = 0;
}
```

By Rachel Morris 11 of 17

```
void Quizzer:: AddTrueFalseQuestion( TrueFalseQuestion* q
14
15
       if ( m_count_tfQuestions >= 3 ) { return; }
16
       m_tfQuestions[ m_count_tfQuestions++ ] = q;
17
18
19

Run and test

Run the program and make sure it works with your code

```
Static arrays can be resized at run-time.
(true/false): false
CORRECT!
Classes can contain member variables and
  functions.
(true/false): true
CORRECT!
It is good practice to set a pointer to nullptr
  when not in use.
(true/false): true
CORRECT!
Which of the following is the address-of
  operator?
OPTIONS:
0. &
1. *
2. ->
3. ::
0
CORRECT!
Dynamic variables are allocated on the...
OPTIONS:
0. stack
1. heap
2. queue
3. array
CORRECT!
When a value is being passed into a function
  call, it is known as a...
```

```
OPTIONS:
0. parameter
1. structure
2. reference
3. argument
3
CORRECT!

Final Score: 6 out of 6
```

By Rachel Morris 17 of 17
